Works on a laptop or a phone. For a quick look, click **Watch a finished run**: a full game plays in about 15 seconds and ends on the scoreboard.

The game

You start with $100 million of one stock on its IPO day, and you can't sell any of it yet. Your job is to turn that one position into lasting family wealth using only what a private bank would offer: sales in open trading windows, a 10b5-1 plan, a zero-cost collar, a credit line against the shares and an index fund. Shares unlock on the dates in the company's real prospectus, and the game enforces the SEC rules that go with them.

There are seven cards. SpaceX is live: it listed in June 2026, and its card gains a day after every market close. The other six are real 2019 to 2021 IPOs played over five years with the name hidden until the end. Three bots with fixed strategies play the same card next to you.

How it fits the prompt

Trading game	One stock plus its derivatives, a fixed $100M stake and a five-year run, scored on Sharpe ratio, max drawdown and after-tax IRR.
Historical data	Daily prices, Treasury rates, earnings dates and each prospectus's lockup terms, stored in the repo.
Updates itself	A GitHub Action runs every weekday night. It pulls new prices, rates, SpaceX option quotes and SEC filings, and republishes the site only if the tests pass (update log, run history).

What Claude did and how we checked it

I started by writing a PRD: what the game is, the rules it has to enforce, where the data comes from, what each screen shows and the tests it has to pass. Claude Code built the app from that document. One session broke the PRD into tasks, handed them to agents working in parallel (data job, game engine, screens, art, tests) and checked each piece before marking it done. The finished site makes no AI calls. Everything Claude produced is saved in the repo as plain files.

9 prospectuses read twice by separate agents (18 reads)	**64** anonymized headlines written; 4 identification rounds	**17** findings from the banker and quant critics	**185** tests pass, with a spreadsheet cross-check	**0** AI calls while you play; the game is static

Lockups, read twice

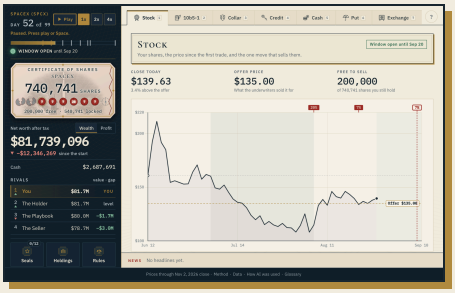

The lockup dates decide when you can sell, so they had to be right. Two agents read each of the 9 prospectuses separately, and each wrote down every release date with the sentence and page it came from. A third agent compared the two reads and settled the 4 places they disagreed by quoting the filing.

Hiding the names

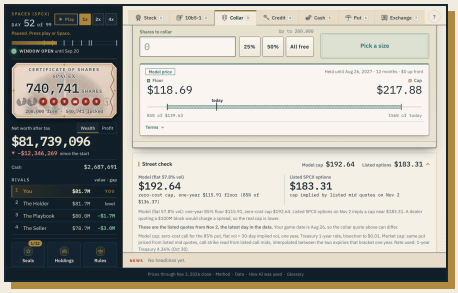

On the six blind cards, Claude wrote a headline for each of the biggest price moves without naming the company. A script rejects any line with the company's name, ticker, products or executives, and then a separate agent tried to guess the company. Four of the six were never identified.

Checking the math

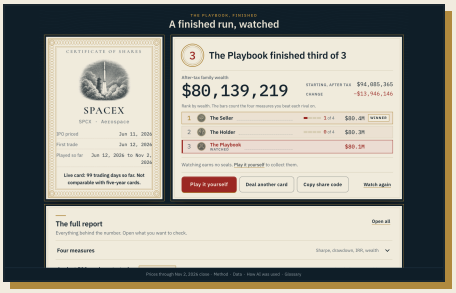

185 automated tests run before any change goes live. Twelve of them have known answers: Black-Scholes, XIRR, Sharpe ratio, max drawdown and the SpaceX unlock schedule, among others. A spreadsheet with live Excel formulas recomputes six of those on its own. Two more agents, one acting as a private banker and one as a quant, tried to break the rules and the numbers. They found 17 problems, such as a 10b5-1 cooling-off period counted from the wrong quarterly report, and each one was fixed or written into the rules as a stated game term.

Playing the SpaceX card.

Pricing a collar, checked against listed options.

The scoreboard against the three bots.
